Infrastructure Project Overview

We propose the construction of the world's highest density source of ultracold neutrons (UCN), the Canadian Spallation Ultracold Neutron Source (CSUNS). The project would be a collaborative effort between Canada, Japan, and the US.

A window of opportunity exists to capitalize on the successes of Japanese collaborators developing new technology to produce UCN, allowing the Canadian project to surpass other proposed sources elsewhere. The UCN source would be located in Canada at TRIUMF, Vancouver, BC. This location is ideal because of the high-intensity high-energy proton beam available, which is used to drive the UCN source. The truly high density that could be obtained at TRIUMF would allow a class of precision measurements of the fundamental properties of the neutron to be conducted with significantly higher precision than any other UCN source. The project would therefore make a major impact on studies of fundamental physics with UCN. Funding for physics experiments would be requested in the future from a combination of NSERC, Japanese, and other international sources. Being the most intense source of ultracold neutrons in the world, the source would attract many international users to Canada.

The UCN source technology is a so-called superthermal source based on downscattering of cold neutrons (CN) in superfluid liquid helium. Neutrons are liberated by proton-induced spallation from a tungsten target. The neutrons are moderated in room temperature heavy water and then 20 K liquid deuterium down to cold neutron energies. The cold neutrons are down-scattered by phonons in superfluid ^4He (He-II) to ultracold neutron (UCN) energies. UCN are transmitted through guide tubes to experiments.

The experiments that would be conducted initially at CSUNS would be a measurements of the neutron lifetime, of neutron energies levels in the earth's gravitational field, and of the neutron electric dipole moment. These are the highest priority experiments for this field.

Project Description

Additional details about the infrastructure, principal area(s) of research to be enabled by the infrastructure and the area of application of the research.

The CSUNS project is a collaborative effort between Canada, Japan, and the US, and would be located at TRIUMF. The infrastructure that is required is as follows: a fast kicker magnet to divert the proton beam to the UCN source, a fully instrumented beamline to deliver the proton beam, a tungsten spallation target and associated handling and cooling equipment, the cryostat containing the UCN source itself and associated cryogenic equipment, and, finally, radiation shielding in the form of steel and concrete blocks. In-kind and matching funds would be supplied by a combination of TRIUMF (NRC) and Japanese sources.

The fundamental neutron physics experiments that would be conducted using the UCN source are as follows:

- * A precision measurement of the neutron lifetime, a critical parameter in astrophysics which can also be used to search for new physics beyond the standard model of particle physics.
- * Precise spectroscopy of the quantized energy levels of neutrons confined above a mirror in the earth's gravitational field. This experiment would test theories of modifications to gravity, predicted by string-theory motivated models involving extra dimensions.
- * A search for a non-zero neutron electric dipole moment. Such an experiment aims to search for an explanation of the predominance of matter over antimatter in the universe, by being a very sensitive probe of new physics beyond the standard model.

The project would represent a new direction in subatomic physics in Canada, and would increase involvement in Canada's scientific program from new users outside Canada.

Unique technologies used in this proposal are cryogenics, vacuum technologies, nuclear instrumentation, RF technology, and superconducting technology. Many of these technologies are common to the medical field, and there is typically a large cross-over in personnel. The neutron transport issues in the UCN source are similar to those encountered in the design of future nuclear reactors. Acsion Industries, a Manitoba business with expertise in this area, has therefore expressed a strong interest in the project and it is probable that some in-kind contribution to the project would come from Acsion. Acsion is also involved in use of nuclear technologies in advanced manufacturing. The project therefore satisfies the People, Knowledge, and Entrepreneurial Advantages mentioned in Canada's S&T priorities. It also promotes world-class excellence by targeting an area of strength in basic research.

Fund Requirements

Explanation of the infrastructure project's classification as a New Initiatives Fund application.

The Canadian Spallation Ultracold Neutron Source project is truly a world-class new initiative which has not previously been supported CFI. The appropriate CFI fund is therefore the New Initiatives Fund (NIF).
