Project title: Canadian Spallation Ultracold Neutron Source

Project Summary

We propose the construction of the world's highest density source of ultracold neutrons (UCN), the Canadian Spallation Ultracold Neutron Source (CSUNS). The project is a collaborative effort between researchers in Canada, Japan, and the United States.

A window of opportunity exists to capitalize on the successes of our Japanese collaborators in developing new technology to produce UCN, thereby allowing the Canadian project to surpass other proposed sources elsewhere. The UCN source would be located in Canada at TRIUMF, Vancouver, BC. This location is ideal because of the already available high-intensity high-energy proton beam, which is used to drive the UCN source. The truly high density that could be obtained at TRIUMF would allow a class of precision measurements of the fundamental properties of the neutron to be conducted with significantly higher precision than at any other UCN source. The project would therefore make a major impact on studies of fundamental physics with UCN. Funding for physics experiments would be requested in the future from a combination of NSERC, Japanese, and other international sources. Being the most intense source of ultracold neutrons in the world, the source would attract many international users to Canada.

The UCN source technology is a superthermal source based on the downscattering of cold neutrons (CN) in superfluid liquid helium. Neutrons are liberated by proton-induced spallation from a tungsten target. The neutrons are moderated in room temperature and 20 K cold moderators. The resultant cold neutrons are down-scattered by phonons in superfluid ^4He (He-II) to UCN energies. UCN are then transmitted through guide tubes to experiments.

The infrastructure that is required is as follows: a fast kicker magnet to divert the proton beam to the UCN source, a fully instrumented beamline to deliver the proton beam, a tungsten spallation target and associated handling and cooling equipment, the cryostat containing the UCN source itself and associated cryogenic equipment, and, finally, radiation shielding in the form of steel and concrete blocks. In-kind contributions to the project would be supplied by a combination of TRIUMF (NRC) and Japanese sources.

The experiments that would be conducted initially at CSUNS would be measurements of the neutron lifetime, of neutron energy levels in the earth's gravitational field, and of the neutron electric dipole moment. These fundamental neutron physics experiments have been identified as the highest priority experiments for this field. The completion of such cutting-edge physics experiments would represent a long-term program in experimental subatomic physics in Canada. Since the Canadian project would produce the highest density of UCN, Canada would thereby lead the rest of the world in this field. Initially, the program would focus on the following suite of experiments:

* A precision measurement of the neutron lifetime. The neutron lifetime is a critical

Applicant institution: The University of Winnipeg

Project no.: 19280

Project title: Canadian Spallation Ultracold Neutron Source

Project Summary

parameter in astrophysics in that the neutron lifetime determines the abundances of light elements in our universe. It is also a critical parameter for accurate determinations of a parameter of the standard model of particle physics V_{ud} . An accurate measurement of this parameter is important for searches for new physics beyond the standard model.

* Precise spectroscopy of the quantized energy levels of neutrons confined above a mirror in the earth's gravitational field. This experiment would test theories of modifications to gravity, predicted by string-theory motivated models involving extra dimensions.

* A search for a non-zero neutron electric dipole moment. Such an experiment aims to search for an explanation of the predominance of matter over antimatter in the universe. A non-zero value found at the current level of sensitivity would also indicate new physics beyond the standard model.

None of these projects can currently be completed in Canada because of a lack of the appropriate infrastructure. The project would therefore represent a new direction in subatomic physics in Canada. The world-leading facility that would be created would increase involvement in Canada's scientific program from new users outside Canada. Many of the other collaborators listed on the proposal who are from outside Canada have never conducted research in Canada before. Their interest in the Canadian project is due to the fact that they want to be involved in this world-leading facility. The Japanese and U.S. collaborators, who are from prestigious institutions in those countries, are already asking for time to use the facility, and would either lead or otherwise be involved in the cutting-edge experiments listed above.

The technology used in the creation of the infrastructure is state of the art. Technologies used in the ultracold neutron source and in the experiments conducted there, are cryogenics, vacuum technologies, nuclear instrumentation, RF technology, and superconducting technology. Many of these technologies are also used in the medical field, and there is typically a large cross-over in personnel. Neutron transport issues in the UCN source are similar to those encountered in the design of future nuclear reactors, and similar to the modern-day use of radiation-related technologies to safety and to advanced manufacturing methods. Acsion Industries, a Manitoba business with expertise in this area, has therefore joined the project and has provided an in-kind contribution to help study these issues.

Over the period of construction and operation of the infrastructure, the project will contribute to the training of a large number of undergraduate students, graduate students, and postdoctoral scholars. These highly qualified personnel would be trained in the use of the aforementioned technologies, and in the science of fundamental physics. Such personnel therefore receive training in some of the most

Project title: Canadian Spallation Ultracold Neutron Source

Project Summary

technologically-advanced science in the world. They are usually highly motivated individuals who can succeed in almost any technological field in today's knowledge-based society in Canada.

The project satisfies the People, Knowledge, and Entrepreneurial Advantages mentioned in Canada's S&T priorities. It also promotes world-class excellence by targeting an area of strength in basic research.

Applicant institution: The University of Winnipeg

Project no.: 19280

Project title: Canadian Spallation Ultracold Neutron Source

Institutional Priority and Commitment

Criterion Standard:

The proposed project is of strategic importance to the institution. The institution has made and will continue to make tangible and significant commitments in support of this area of strategic priority. These commitments are, or will be, of direct benefit to the proposed project, including the attraction and retention of the best researchers.

Each of following aspects must be addressed:

1. Describe the significant support that the institution has provided to this area of research (e.g., institutional resources committed to capitalize on the proposed infrastructure, the creation of new research positions, or research chairs in these areas, etc.).
2. Describe the significant and tangible contributions that the institution will make to the current and on-going needs of the proposed project.
3. Explain why this project is important to the fulfillment of the institution's strategic research plan.

The requested Canadian Spallation Ultracold Neutron Source (CSUNS) would be home to the world's most advanced ultracold neutron (UCN) source. CSUNS would put Canada on the map as the leader in UCN research and is the next phase of research development in this area of experimental subatomic physics. Housed at Canada's National Laboratory for Particle and Nuclear Physics, TRIUMF, this infrastructure would be used by researchers from across the country and around the world.

In 2004 The University of Winnipeg hired Dr. J. Martin to become one of four subatomic physicists at the University, and the sole experimental subatomic physicist. Since this time, Dr. Martin has become a leader in the area both nationally and internationally. His success can be seen in the numerous collaborative research projects and publications where he has played a significant role, the number of graduate students and postdoctoral fellows who come to The University of Winnipeg specifically to work with him, and in the creation of this innovative, international project. The level of support from Japanese collaborators and TRIUMF for this project is proof that only excellent researchers such as Dr. Martin, can marshal such a comprehensive infrastructure project to go forward with pioneering research in the area of subatomic physics. In 2006 Dr. Martin was awarded CFI funding under the Leaders Opportunity Fund for his Subatomic Physics Detector Laboratory at The University of Winnipeg. This lab is very active and is the hub for HQP training in subatomic physics at the University. The University initially supported the construction of the lab with a contribution of \$5,419 for test equipment which formed a critical component of the Subatomic Physics Detector Laboratory. Through internal research funding, Dr. Martin has received approximately \$8,000 for research-related expenses such as equipment, supplies, student research assistants, and travel. The University has also provided Dr. Martin with a teaching release of one full course per year, in order to provide him with more time for research and training. The strong support and interest in Dr.

Applicant institution: The University of Winnipeg

Project no.: 19280

Project title: Canadian Spallation Ultracold Neutron Source

Institutional Priority and Commitment

Martin's work from national and international collaborators can be linked to the time and commitment Dr. Martin has for this research project. In-kind support has also been provided to the Subatomic Physics Detector Laboratory in the form of administrative assistance from Financial Services and the Research Office, along with facilities for meetings and general operation and building costs.

In experimental subatomic physics, it is vitally important to focus efforts at national facilities like TRIUMF. The University recognizes and fully supports this need of Prof. Martin to advance his research goals and his field. The project will lead to new future partnerships between the University of Winnipeg and TRIUMF, which are being investigated at this time. The University anxiously looks forward to a formalized relationship with TRIUMF. The University sees this infrastructure as a very large investment in our future research and training program. We are well aware that this international project will be clearly identified for many years to come as having been first initiated because of support from the University of Winnipeg, and we are excited to see it come to fruition. We will be supporting this immense project through continued internal research and travel support for faculty and students involved in research at CSUNS, and well as continued course releases for Dr. Martin and other faculty involved in research projects at CSUNS. Beginning in the 2009-10 academic year, Dr. Martin will also be receiving an additional course reduction. In-kind support will be provided for this project through administrative assistance from Financial Services and the Research Office, technical support through the Technology Solutions Centre, and facilities for meetings and workshops.

The University of Winnipeg affirms that this project is a major investment in our future research and training program. The University of Winnipeg has a strong commitment to the education and training of students at all levels, and prides itself on the active research in which our students, especially at the undergraduate and Masters level are participating. The projects which will be conducted at CSUNS will be world renowned, cutting edge research and our students will be a part of it. The scope of training opportunities for HQP from The University of Winnipeg is tremendous and will give our students phenomenal experience which will be very useful for them whether they continue on to graduate school or a career in industry. The research conducted at CSUNS will be highly collaborative in nature, with scientists from around the world participating in experiments at the facility. The international interest on this project is clear, given the generous support of our collaborators in Japan. Dr. Martin is a member of numerous groups working on experiments, which include academics from Asia, Europe, the United States, and various institutions across Canada. With this infrastructure, Canada will become the world leader in experimental subatomic physics, and will be home to the world's highest density ultracold neutron source. International collaborative projects will be spawned within Canada and will increase in number, size, and prestige. Along with the enhancement of research, training of HQP,

Applicant institution: The University of Winnipeg

Project no.: 19280

Project title: Canadian Spallation Ultracold Neutron Source

Institutional Priority and Commitment

and the continuation of interdisciplinary, collaborative research work, this project will also be involved in expanding the academic-industry relationships of the University. The University recently signed a memorandum of understanding with Acsion Industries (Pinawa, Manitoba) to assist this project. The partnership with Acsion Industries was strongly encouraged through new University programs supporting partnerships between the public and private sector. Because of Prof. Martin research program, we've taken action to expanded those partnership programs significantly. This partnership is also part of the University's continuing advancement of commercialization and technology transfer efforts.

Quality of the Research or Technology Development

Criterion Standard:

The research opportunity is timely and has the potential to lead the breakthroughs in research or technology development. The proposed research or technology development is innovative and at the leading edge internationally.

Each of following aspects must be addressed:

1. Describe the proposed research or technology development activity and the potentially transformative and innovative aspects of this endeavour.
2. Explain why it is important to pursue the proposed research or technology activity at this time.
3. Explain how the proposed research or technology development activity complements or differs from comparable research or technology development being conducted nationally and/or internationally.

1. Proposed Research and its Transformative and Innovative Aspects

1.1 Introduction: Ultracold Neutrons and Sources

Ultracold neutrons (UCN) are neutrons of such remarkably low energies that they are totally reflected from the surfaces of a variety of materials. Hence, UCN can be stored in bottles for long periods of time, whereas higher-energy neutrons would either pass through or be captured in the walls of the bottle. Typically, UCN have kinetic energies that are less than 300 neV. Correspondingly, UCN are strongly affected by various fields, such as the Earth's gravitational field, and by strong magnetic fields (7 T).

The difficulty encountered historically in producing UCN has been to liberate them from atomic nuclei, and then efficiently and effectively cool the neutrons without suffering large losses. In the past decade, a new method of cooling the neutrons has come been developed. Based on a technique from condensed matter physics, sources that employ this method of cooling are known as superthermal sources.

The advent of superthermal sources of UCN is just now beginning to transform the landscape of fundamental neutron physics. These sources have now demonstrated UCN densities surpassing all previous sources. Sources are being proposed at various facilities in the world. Our proposal is to construct The Canadian Spallation Ultracold Neutron Source (CSUNS). As will be explained in section 3, this project would exceed the capabilities of all planned future UCN sources worldwide. The source would provide the highest density of UCN ever achieved, and would enable the most precise measurements in fundamental neutron physics ever conducted.

1.2. Proposed Research Activity at CSUNS

Applicant institution: The University of Winnipeg

Project no.: 19280

Project title: Canadian Spallation Ultracold Neutron Source

Quality of the Research or Technology Development

Given the new technology that has led to this breakthrough in UCN production, a variety of new UCN experiments can be envisioned that can now be conducted with higher precision than ever before. We have considered a variety of physics experiments that could be done with the Canadian source, and have decided to focus in the short term on the three experiments with highest scientific priority for the field:

- * a precise measurement of the neutron lifetime,
- * characterization of the recently discovered UCN quantum states in the Earth's gravitational field, and
- * a search for a non-zero neutron electric dipole moment.

Each project has its own physics interest and timeline, so that, in time, a series of UCN experiments would be performed at the CSUNS facility.

The funding that we are requesting in this proposal is for the UCN source, CSUNS, alone. The experiments themselves are significant undertakings. The experiments would be supported by a combination of NSERC, Japanese, U.S., and other international sources. These cutting-edge experiments, each with their own physics interest in searches for new physics beyond the Standard Model, justify the construction of CSUNS.

Presented below is a brief description the physics motivation, timeline, and the current status and collaborators involved in each experiment, assuming the superthermal UCN source (CSUNS) were to exist.

1.3 Neutron Lifetime

Precise measurements of the neutron lifetime are of physics interest primarily for two reasons:

- * The neutron lifetime is an essential parameter for Big-Bang Nucleosynthesis (BBN) calculations, and is currently the dominant uncertainty for accurate BBN predictions [1].
- * The neutron lifetime can be used, in combination with measurements of angular correlations in neutron decay, to extract the Cabibbo-Kobayashi-Maskawa (CKM) matrix element V_{ud} . V_{ud} is the most precisely measured, large parameter in the CKM matrix and is useful for a variety of tests of the unitarity of the CKM matrix. Lack of unitarity would signify new physics beyond the standard model. Currently, V_{ud} is most precisely determined from superallowed nuclear decays. UCN lifetime experiments offer

Applicant institution: The University of Winnipeg

Project no.: 19280

Project title: Canadian Spallation Ultracold Neutron Source

Quality of the Research or Technology Development

an independent check of the nuclear extraction, free of nuclear corrections.

Figure 1 (on page 5.11) displays the current status of the CKM matrix element V_{ud} . It also displays the current status of previous experimental results for the neutron lifetime. There exists a seven sigma discrepancy between the most recent precise measurement of the neutron lifetime (878.5 ± 0.8 s, [2]), and the average of all previous measurements (885.7 ± 0.8 s, [3]). The most recent precise measurements have been performed in traps formed by the mean Fermi potential of material walls [4, 5] or material walls in combination with gravity [2]. The largest systematic uncertainties in these experiments arise due to effects of the interactions of the UCN with the material walls of the trap. At TRIUMF, a magneto-gravitational trap would be used to confine the neutrons, thus removing such effects. Similar projects with magnetic trapping of UCN have been discussed in the context of experiments at Los Alamos National Laboratory (LANL) [6], and elsewhere [7, 8, 9]. Our project would build on preliminary research performed at LANL, achieving better precision at CSUNS because of the increased density of UCN that would be available there.

The new magnetic trap experiments have identified an important new systematic effect specific to magnetic traps: marginal trapping of UCN with energies larger than the trap depth. These quasi-trapped UCN can escape from the trap with timescales similar to the neutron lifetime, potentially giving a large systematic effect. These UCN must therefore be removed from the trap rapidly so that measurements of the UCN lifetime can be performed. The LANL trap design deals with this problem by introducing chaotic neutron orbits within the trap so that the quasi-trapped UCN rapidly sample their allowed phase space and escape. New ways of cleaning these UCN from the trap will be discovered at LANL, thereby making the statistical uncertainty dominant. The higher UCN density available at CSUNS would then be used to reduce the statistical uncertainty.

1.3.1 Neutron Lifetime Experiment for CSUNS

The magneto-gravitational trap from LANL [6] is designed to contain field-repelled neutrons, i.e., neutrons in a positive-energy eigenstate of the spin-field interaction. Figure 2 (on page 5.12) shows a diagram of the trap for CSUNS, which would be based on the LANL design. The design calls for an open-top magneto-gravitational bowl trap with two independent magnetic-field-generating components: high-strength neodymium-iron-boron (NdFeB) permanent-magnet (PM) Halbach arrays [10, 11] that form the open-top bowl-shaped trap surface, and an enveloping set of current-carrying window-frame coils outside of the bowl.

The PM arrays produce a field in the trap volume that is 1 T at the surface and falls

Applicant institution: The University of Winnipeg

Project no.: 19280

Project title: Canadian Spallation Ultracold Neutron Source

Quality of the Research or Technology Development

off exponentially in normal distance from the PM array surface with a characteristic length of about 1 cm; the PM field is the main confining field of the neutrons. The effective trap volume is 0.6 cubic metres. The window-frame coils produce a field of approximately 0.05-0.1 T that is everywhere perpendicular to the dominant component of the PM-array field and performs two essential functions: first, to guarantee that the trapped neutrons never encounter a zero field magnitude, and second, to guide the decay electrons to the detectors at the two ends of the trap. Under these conditions, neutrons with low enough kinetic energy are perfectly reflected from the field near the trap surface, and if their kinetic energy at the bottom of the trap is small enough to not exceed the trap height, they would stay in the trap for an effectively infinite time, except for their natural decay.

Neutrons are fed into the trap through a mechanically operated trap door at the bottom of the trap. The upper surface of the trap door is covered with a Halbach linear PM array in such a way that when the door is closed, the combination of the trap-door PM array and the PM arrays on the trap surface around the door opening forms a continuous Halbach array without gaps. The trap door will be opened and closed by an actuator below the bottom of the trap. Calculations have shown that forces on the trap door are manageable from the point of view of the mechanical actuator (on the order of about 800 N in the worst-case position).

Quasi-trapped neutrons are removed during the filling/cleaning phase of operation by a neutron-absorbing clean-out surface that is lowered to a height that is approximately 5-10 cm below the top of the bowl. The clean-out surface is then withdrawn to a level above the top of the trap after the trap door is closed and before counting of neutron decays for the lifetime measurement is started. In order to facilitate removal of quasi-trapped neutrons, the bowl has shallow inclination angles on one side and at both ends that force neutrons to acquire a large vertical velocity component at some point along their trajectories and then reach a sufficient height to strike a clean-out absorber. Moreover, chaotic orbit behavior is induced by ripples in the permanent-magnet field.

A prototype of the trap is under construction at LANL. Individuals from that collaboration who have joined the TRIUMF UCN effort are: J.D. Bowman, B. Filippone, T. Ito, and B. Plaster. Since it is already in development, and would have a relatively short running time, the neutron lifetime experiment is a candidate for the first fundamental physics experiment at CSUNS.

A measurement of the neutron lifetime with precision <1 s, but performed in a magnetic trap free of the systematic uncertainties which hinder material traps, would be a very exciting achievement for this field. Such an experiment could be completed at CSUNS in the 2013 time frame. The superior UCN density achieved there would be instrumental in

Applicant institution: The University of Winnipeg

Project no.: 19280

Project title: Canadian Spallation Ultracold Neutron Source

Quality of the Research or Technology Development

achieving the < 1 s statistical error bar required.

1.4 Gravity Levels Experiment and Plans for CSUNS

Recently, a group at Institut Laue-Langevin (ILL, Grenoble, France) has successfully observed for the first time the quantization of the energies of neutrons confined above a UCN mirror in the Earth's gravitational field [12]. The experiment is an interesting application of quantum mechanics to micron-sized quantum states. The experimental result has been used to place limits on modifications to the short-range (10 micron) behavior of gravity. The result therefore has impacted theories involving micron-scale extra dimensions. The result has also been used to constrain axion models [13].

The same group at ILL is mounting a more advanced experiment (the GRANIT experiment) in which they would attempt to excite resonant transitions between gravitational levels in a UCN bottle, achieving better resolution in the level spacing and hence placing tighter constraints on theories.

These experiments are limited in their scope by the UCN density available at ILL. TRIUMF therefore would have a distinct advantage for a new experimental effort. Additionally, this is a relatively new avenue of research in the UCN community, and much progress is being made rapidly. A timely experiment at TRIUMF would have a large impact on the field.

The experiment would take roughly one year to complete. The design of the experiment and the main detector are underway in Japan. This being the case, and owing to the short run time for the experiment, this experiment is therefore also a candidate to be one of the first fundamental physics experiments to be conducted using the UCN source at TRIUMF.

1.5 Neutron Electric Dipole Moment (n-EDM)

Electric dipole moments for fundamental particles are forbidden by time-reversal symmetry. The small amount of CP violation in the standard model leads to very tiny EDM's (for the neutron EDM, 10^{-31} e-cm). However, new sources of CP violation beyond the standard model are required to account for the observed baryon asymmetry of the universe. In many models of physics beyond the standard model, extra sources of CP violation are often present. Such models often naturally generate n-EDM's at the 10^{-27} e-cm level [14]. The current experimental limit on the n-EDM is $d_n < 3 \times 10^{-26}$ e-cm [15]. The next generation of experiments at ILL, Paul Scherrer Institut (PSI, Villigen, Switzerland), and the Spallation Neutron Source (SNS, Oak Ridge, TN, USA) aim

Applicant institution: The University of Winnipeg

Project no.: 19280

Project title: Canadian Spallation Ultracold Neutron Source

Quality of the Research or Technology Development

to constrain the n-EDM to the 10^{-27} - 10^{-28} e-cm level. The aim of an experiment at CSUNS would be a determination at the 10^{-28} e-cm level.

1.5.1 Experimental Principle

Neutron EDM measurements use Larmor precession of the neutron spin under a static magnetic field and a static electric field. The effect of an n-EDM is extracted upon electric field (E) reversal. The phase shift that would be induced by a non-zero n-EDM in the electric field is measured by means of neutron polarimetry and hence the neutron electric dipole moment d_n is extracted.

The statistical uncertainty on the EDM is minimized for the largest number of neutrons sampled. For experiments where the experimental volume is smaller than the UCN source volume, it is UCN density that is therefore the most important factor, and CSUNS will be the world leader in UCN density.

Systematic errors that reverse sign with E reversal must also be carefully controlled. Systematic effects arise due to magnetic field instability, due to changes in magnetic field induced by leakage currents, and due to motional magnetic fields in the rest frame of the neutron. To correct for magnetic field instabilities, a comagnetometer is used. The comagnetometer is simply an atomic species which samples the same fields experienced by the neutrons, and whose Larmor precession can also be measured.

In the highest precision experiments, an additional systematic effect must be considered which arises from magnetic inhomogeneity and relativity: the recently discovered geometric phase effect [16, 17, 18]. This effect arises due to a combination of magnetic field inhomogeneity and neutron motion when the neutrons confined in a trap. Future experiments must carefully account for this effect in their design, which any effort at CSUNS would certainly do.

1.5.2 Previous n-EDM experiments

In the previous ILL experiment, UCN were confined in a 50 cm diameter, 12 cm tall cell, in a 1 uT magnetic field and a 12 kV/cm electric field. The result for the upper limit on the n-EDM was $d_n < 3 \times 10^{-26}$ e-cm, with the precision limited by statistics. The UCN density in the EDM cell was 0.7 UCN/cc.

A co-magnetometer of ^{199}Hg was used; hence magnetic field fluctuations were well normalized. Systematic errors associated with E reversal were controlled to better than 10^{-27} e-cm. The false EDM due to the geometric phase effect was characterized as

Applicant institution: The University of Winnipeg

Project no.: 19280

Project title: Canadian Spallation Ultracold Neutron Source

Quality of the Research or Technology Development

a function of the field gradient to reduce the systematic error arising from that effect.

1.5.3 Future n-EDM Experiments

A broad variety of novel, cutting-edge techniques are being pursued for the next generation of n-EDM searches. Some of the proposed techniques have not been proven experimentally, yet. An n-EDM experiment at CSUNS would build on research completed by the most successful of the three major experimental groups pursuing measurements at this time. We now review these future efforts which will first occur elsewhere.

A new n-EDM measurement at ILL (the CryoEDM experiment) will use a double cell (24 cm diameter and 4 cm height for each cell) with UCN of density 1000 UCN/cc. The cells will reside in a superfluid helium volume. This volume will also be used to produce the UCN by downscattering neutrons in a CN beam from the ILL reactor. A superconducting magnetic shield will minimize systematic errors associated with field instability. For one cell, an electric field of 40 kV/cm will be applied while, for the other cell, no electric field will be applied. Neutrons in the second cell will hence be used as a magnetometer, but no co-magnetometer will be present in the measurement cell in the initial phase of the experiment.

A group using the future UCN source at PSI is also preparing an n-EDM experiment. They will carry out a preliminary measurement at ILL with the previous EDM cell of ILL. A measurement of 5×10^{-27} e-cm will then be conducted at PSI from 2009 to 2010. Though the experiment uses the former experimental apparatus from ILL, several innovations will be made to achieve the experimental goal at PSI. The UCN density in the EDM cell will be 1000 UCN/cc. The experiment will employ several magnetometers outside the EDM cell. They are aiming for a precision of 5×10^{-28} e-cm in measurements from 2011 to 2015 [19].

A new n-EDM measurement employing a unique experimental technique is also in preparation for the SNS [20]. A schematic diagram of the apparatus to be used for SNS is shown in Fig. 3 on page 5.12. A cold neutron beam from the SNS will impinge upon a volume of superfluid ^4He creating 150 UCN/cc. The n-EDM measurement will be conducted in the same volume. A small amount of polarized ^3He introduced into the superfluid ^4He will act as a co-magnetometer. A dressed spin technique will be used, where the neutron spin precesses with the same frequency as the ^3He spin. The neutron spin will be aligned with the ^3He spin, so that essentially no neutron captures will occur. Any small effect caused by a non-zero EDM will modulate the capture rate on E-reversal. The capture rate will be measured by sensing scintillation light produced in the helium itself by the capture products. The goal precision is 10^{-28} e-cm. Many technical

Applicant institution: The University of Winnipeg

Project no.: 19280

Project title: Canadian Spallation Ultracold Neutron Source

Quality of the Research or Technology Development

challenges must be overcome for the experiment to be successful, for which novel designs are being pursued. The geometric phase effect for the ^3He magnetometer can be large compared with ^{199}Hg , but is mitigated because of collisions with the surrounding ^4He [17, 18]. Measurements at the SNS will begin in 2013 [21].

1.5.4 Plans for n-EDM at CSUNS

We envision that any n-EDM effort at TRIUMF would occur after the completion of the new round of n-EDM measurements at ILL, PSI, and SNS, in the time frame of 2015 and beyond. It is difficult to say at this time which of these differing techniques would be shown to be the most successful by that time, and which would be best able to use the increased statistical precision which would be possible at TRIUMF. One possible scenario for the initial and fast completion of an n-EDM project at TRIUMF would be to move the most successful device from e.g. ILL or SNS to TRIUMF. This is similar to the initial PSI strategy of beginning with the former ILL apparatus. To take advantage of the higher UCN density at TRIUMF for systematic error reduction, a new and significantly smaller measurement cell would be designed to reduce the size of the geometric phase effect.

Researchers (Use of the Infrastructure)

Criterion Standard:

The principal users of the infrastructure are experts in the relevant research or technology development domain. The research group has the expertise and experience to lead the proposed endeavour.

Each of following aspects must be addressed:

1. Demonstrate that the research group is comprised of highly accomplished researchers and may also include new researchers who have demonstrated potential for excellence and leadership in all the proposed field(s), or experts in technology development who have been recognized for their accomplishments. If any principal users are to be recruited, describe the recruitment plan.
2. Explain how each principal user will use the infrastructure to contribute to the proposed research or technology development.
3. Describe the existing or emerging collaboration and complementarity among the principal users.
4. Demonstrate that the principal users/team have the research or technical expertise to capitalize on the use of the requested infrastructure.

1 Accomplishments and Expertise of Principal Users

The principal users listed on the proposal all have demonstrated track records of significant achievements in experimental subatomic physics. They are well-respected internationally in the subatomic physics community.

The project leader, J. Martin, was a driving force behind the construction of the UCN source at Los Alamos National Laboratory (LANL) and was a leader in the experiments subsequently conducted there. The LANL UCN source currently holds the world record for highest UCN density achieved at 145 UCN/cc. This has served as the first and to date most impressive validation of the superthermal technique that we will use to produce UCN. Also, he has been a leader in the UCNA project at LANL, where his research has focused on detector development, and on the study of systematic effects due to backscattering of low-energy electrons from the surfaces of detectors. Prof. Martin performed research at two of the most prestigious universities in the U.S.: MIT, where as a graduate student he performed the first extraction of the gluon contribution to the proton's spin from high transverse momentum pions; and Caltech, where as a postdoctoral fellow he completed the LANL work and experiments in electron scattering on the contribution of strange quarks to the nucleon form factors. He is currently leading two major detector projects in the Q-weak experiment at Jefferson Lab.

The research group of J. Martin, J. Birchall, C. Davis, M. Gericke, E. Korkmaz, S. Page, and W. van Oers has successfully completed difficult parity-violation experiments at various labs. With recent arrival of new faculty members (J. Martin and M. Gericke)

Applicant institution: The University of Winnipeg

Project no.: 19280

Project title: Canadian Spallation Ultracold Neutron Source

Researchers (Use of the Infrastructure)

the group has renewed its interest in fundamental physics with UCN and CN. The group is currently involved in a large project to make the world's most precise determination of the weak mixing angle from e-p elastic scattering at Jefferson Lab (the Q-weak experiment) which will be installed next year. Though these Canadians and their group represent only 10% of the Q-weak collaboration, they are arguably the most well-known and effective group contributing to the project. This includes leadership since S. Page is the spokesperson of the collaboration.

M. Gericke, S. Page, and J. Martin are leaders in future experiments at the SNS (Spallation Neutron Source, Oak Ridge, TN), as well, primarily experiments on neutron beta-decay and neutron hadronic weak interactions. M. Gericke, in particular, is the spokesperson of an experiment to measure parity-violating capture of neutrons on ^3He . He also serves on the executive committee of the npdgamma experiment.

J. Martin and M. Gericke both have successfully obtained funding from the CFI LOF for detector fabrication and testing facilities at their respective universities. Infrastructure for these laboratories will be used to support detector fabrication for the future experiments at CSUNS.

J. Birchall, C. Davis, S. Page, and W. van Oers have been involved in experiments at TRIUMF to measure medium-energy neutron scattering from light nuclear targets to study the strong force.

The group also has demonstrated a strong commitment to service in the scientific community. S. Page is serving as president of the Canadian Association of Physicists. W. van Oers represents Canada on several high-profile subpanels of the International Union of Pure and Applied Physics. Both have served on the Grant Selection Committee for NSERC Subatomic Physics (GSC-19).

The group has been enhanced significantly by two other researchers well-known in the Canadian community: M. Hayden and L. Buchmann.

M. Hayden is a leader in UCN production in superfluid He and has recently authored a paper in Physical Review Letters on the characterization of ^3He impurities in superfluid ^4He . This paper is related to the development of the SNS n-EDM project. He is very well-respected in the UCN community for these more recent achievements. He is also regarded as a world's expert on low-field NMR techniques and on novel magnetic field sensors (SQUID's) used in such experiments. He is a collaborator on the ALPHA experiment at CERN the goal of which is to perform the first trapping of antihydrogen for spectroscopy.

L. Buchmann has been the main proponent of a possible far-future experiment at CSUNS on

Applicant institution: The University of Winnipeg

Project no.: 19280

Project title: Canadian Spallation Ultracold Neutron Source

Researchers (Use of the Infrastructure)

ion-neutron interactions where the UCN source would be used as a free neutron target. He is well-known for his research on nuclear structure, nuclear astrophysics, and fundamental symmetries in nuclei. He is most famous for being a principal driving force behind the Isotope Separator and Accelerator (ISAC) project at TRIUMF. He is a collaborator on the DRAGON and TUDA projects at TRIUMF.

There is also a great deal of expertise available at TRIUMF. The laboratory clearly has the capability to construct the proposed source, and the commitment of TRIUMF has been demonstrated by substantial contributions to the project. Future hires of new scientific staff would be made at TRIUMF in the area of fundamental symmetries, and such personnel would potentially conduct research using both CSUNS and the TRIUMF ISAC project. We note a large degree of complementarity between the two projects.

Y. Masuda is the leader of the UCN source development project in Japan. He is a well-recognized researcher in the field of neutron physics. In the past several years he has dedicated all his research power to his successful and published technique of coupling a superfluid 4He UCN source to a spallation-driven target. It is his demonstrated source that will form the foundation for the CSUNS project. He is also well-known for his ground-breaking work in fundamental T and P violating processes in nuclei, and in neutron-nucleus interactions.

2 Contributions of Principal Users to the Proposed Research

Each principal user has already contributed to the development of the physics experiments and facility case for CSUNS and will continue to do so into the future. Once the project is underway, the collaborators will dedicate themselves to the successful completion of the neutron lifetime experiment. Y. Masuda, M. Hayden, and J. Martin would also perform the n-EDM development work that would be conducted simultaneously. The principal users are also involved in the management structure of the project, as will be discussed in the "Management" section.

3, 4 Existing and Emerging Collaborations, Complementarity, and Technical Expertise

The existing CSUNS collaboration (including other users) is expected to grow if funds are granted by CFI. At that time, more individuals across the world working on similar projects would be invited to join the project.

The collaboration already has a lot of complementarity among its principal users. The complementarity span a variety of aspects; the users are at various stages in their respective careers, and the topics studied in their research span a broad variety of

Applicant institution: The University of Winnipeg

Project no.: 19280

Project title: Canadian Spallation Ultracold Neutron Source

Researchers (Use of the Infrastructure)

topics. In particular we note the expertise of M. Hayden in condensed matter physics; he has a detailed understanding of the basic physics mechanisms behind the operation of the UCN source. This expertise, coupled with Y. Masuda's and J. Martin's practical experience in constructing UCN sources, and combined with the expertise of the other principal users in conducting difficult subatomic physics experiments has led to a vibrant and active collaboration. The collaboration is one with the required technical expertise to complete the infrastructure project and the research to be done there.

Applicant institution: The University of Winnipeg

Project no.: 19280

Project title: Canadian Spallation Ultracold Neutron Source

Need for the infrastructure

Criterion Standard:

The infrastructure requested is appropriate and essential to support the proposed activities. It will establish or enhance a unique and important institutional capability in an area of leading edge research or technology development.

Each of following aspects must be addressed:

1. Explain why the requested infrastructure is appropriate for the proposed research or technology development.
2. Explain why the proposed research cannot be supported using existing infrastructure.
3. Describe the availability of similar infrastructure within the institution, the region, the country, and/or internationally and address any issues of accessibility, complementarity, duplication, and sharing.

1 Appropriateness of the Requested Infrastructure for the Proposed Research

1.1 Introduction

The fundamental physics experiments envisioned for CSUNS (described in the "Quality of the Research" section) all have one feature in common: they are currently limited by the statistics achievable in the experiment. For this reason, it is the achievement of the highest possible densities of UCN which is the most important factor.

The UCN source technology that will be used at CSUNS is a superthermal source based on downscattering of cold neutrons (CN) by phonon production in superfluid 4He [23]. Figure 4 (on page 9.8) displays a schematic diagram of the UCN source.

Neutrons are liberated by the highly efficient process of proton-induced spallation from a tungsten target using the 500 MeV TRIUMF proton beam. It is the combination of these two features (spallation, combined with 4He technology) that sets the CSUNS project apart from the all other sources worldwide. This source technology has been developed by Y. Masuda's group in Japan. Using a prototype source at the Research Center for Nuclear Physics (RCNP) Osaka, a UCN density of 10 UCN/cc has already been achieved.

It is primarily the superior proton beam power in Canada (at TRIUMF) that would lead to the creation of truly high densities of UCN. Since UCN production scales with beam power, this results in a predicted increase in UCN density by a factor of 51 when operated in Canada. This, coupled with incremental gains from changes in geometry and UCN guide technology resulting in an additional factor 20 gain, will give rise to UCN densities exceeding 10,000 UCN/cc at CSUNS.

Applicant institution: The University of Winnipeg

Project no.: 19280

Project title: Canadian Spallation Ultracold Neutron Source

Need for the infrastructure

1.2 UCN Production

A new generation of superthermal UCN sources is being developed at many institutes in the world, and these developments make neutron physics an exciting and vibrant field. In the previous generation (the turbine source at Institut Laue-Langevin, ILL, Grenoble, France) the UCN density was limited by Louisville's theorem. The new UCN sources use phonons for neutron cooling, and are free from the phase space limitation of the neutrons themselves.

UCN are created in superthermal sources by transporting CN into a region of material where phonons can be created. Important parameters for a source of this type are:

- * CN flux
- * lifetime of UCN in the material
- * production rate of UCN from CN

For higher UCN production, a higher CN flux is preferable. However, with higher CN flux comes a higher heat load, which is dominated by gamma's from neutron capture in the surrounding material. For a 4He production volume, the UCN storage lifetime is limited by phonon up-scattering, which strongly depends on temperature, and the lifetime would be severely affected if the heat transport out of the source material couldn't be dealt with. Fortunately, the superfluid 4He has essentially infinite thermal conductivity, and heat can be removed very effectively. The UCN production rate is given mainly by CN's producing single phonons in the 4He . Multiphoton excitations also contribute, making effective use of higher-energy CN.

After production, UCN are extracted to a UCN guide and a storage bottle for experiments. Extraction efficiency from the source material to the UCN guide and transport efficiency to the storage bottle are important parameters to obtain higher UCN density for experiments.

1.3 The Prototype CSUNS Source at RCNP, Osaka

The Canadian source will be based on the source of Y. Masuda, which is currently installed at the Research Center for Nuclear Physics (RCNP), Osaka University, in Osaka, Japan. The source uses a Pb spallation target and the UCN production material is superfluid 4He . The source has been used to characterize UCN production from superfluid 4He [23]. A picture of the source, as it exists in Osaka, is shown in Fig. 5 (on page 9.9).

Applicant institution: The University of Winnipeg

Project no.: 19280

Project title: Canadian Spallation Ultracold Neutron Source

Need for the infrastructure

The UCN production volume is a 10 L vessel containing superfluid helium, located within a 20 K heavy water vessel, in turn located within a 300 K heavy water vessel. The incident proton beam is operated at 390 MeV and at 1 uA.

In an experiment conducted at RCNP in 2007, UCN were extracted from the 4He to a vertical UCN guide of 1.2 m height and transported to an experimental port through a horizontal UCN guide of 3 m length. At the experimental port, the UCN density was 10 UCN/cc at $E_C=90$ neV. E_C is the maximum UCN energy, determined by the properties of the guide material used. The UCN storage lifetime was 30 s. The results are consistent with a model of neutron transport and phonon production in the source. For the model, an important consideration is the inclusion of multi-phonon excitations in the superfluid 4He. These excitations allow higher energy neutrons to be downscattered thereby increasing the UCN production rate [24]. The result shows that UCN losses upon extraction from the superfluid helium and transport through the UCN guides are small.

1.4 Canadian Spallation Ultracold Neutron Source Parameters

At TRIUMF, the 500 MeV proton beam will be used at 40 uA current. The production scales approximately proportional to beam power, giving a factor 51 projected increase in UCN density over the prototype UCN source at RCNP, Osaka. Other gains will be had from a reconfiguration of the source. The configuration of the superfluid 4He (He-II) in the source will be altered from the present vertical arrangement at RCNP to the horizontal arrangement displayed in Fig. 4 (on page 9.8). In this way, the CN flux in the He-II will be doubled simply by decreasing the average distance of He-II from the spallation target.

A UCN density in the 4He of 55,000-110,000 UCN/cc is expected internal to the superfluid volume, where a conservative storage lifetime of 150 s is assumed (limited by wall losses, and to a lesser extent phonon upscattering). After production, UCN are extracted horizontally into a UCN guide, and transported to experiments. Horizontal extraction gives another relative gain over the RCNP prototype source. Taking all factors into account, the UCN density at the experimental port of the CSUNS source would be 10,000 UCN/cc at $E_C=90$ neV. The horizontal guide quality will be improved over $E_C=90$ neV, however we keep the estimate of 10,000 UCN/cc as a conservative estimate.

The UCN source will initially use 20 K heavy water (D2O) as the cold neutron moderator, which we intend eventually to upgrade to liquid deuterium (LD2). D2O is preferred initially for its comparability to the existing Japanese source, the simpler safety issues compared to LD2, and due to cost considerations. The disadvantage of D2O at 20 K, is that the CN temperature will be 80 K, while for LD2 it would be truly 20 K. D2O is therefore not as well-matched to the phonon dispersion curve in superfluid 4He. The

Applicant institution: The University of Winnipeg

Project no.: 19280

Project title: Canadian Spallation Ultracold Neutron Source

Need for the infrastructure

better matching of LD2 would increase the relevant CN flux, resulting in an eventual UCN density of 50,000 UCN/cc.

The comparison of some of the parameters of this source to the rest of the world's UCN projects is summarized in Table 1 (on page 5.11). For CSUNS, the numbers for both D2O and D2 moderators are included.

The beam power we can accept is limited by gamma heating from neutron captures in the surrounding material. According to a computer simulation, the power deposited by gamma heating in the superfluid is 8 W for our operating proton beam power of 20 kW. Fortunately, this heat can be quickly removed by making use of the excellent thermal properties of superfluid helium to transfer the heat rapidly to a 3He cryostat and through a heat exchanger. As a result, the heat is transferred to 3He gas via 3He vaporization, and then removed by 3He pumping. The latent heat of 3He is 35 J/mol. The cooling power of the 3He pumping is represented as the product of the latent heat of vaporization, the vapor pressure, and the pumping rate, divided by RT , where R is the ideal gas constant and T temperature. The saturated vapor pressure of 3He is 3 Torr at 0.8 K. Therefore a pumping speed of 10,000 cubic meters per hour applied to the 3He at 3 Torr removes 17 W of heat. To further reduce the heat load, a CN filter will be placed between the spallation target and the superfluid 4He volume, thereby reducing the number of hotter neutrons entering that volume.

Therefore, we estimate that the heat loads expected for instantaneous 20 kW beam power are well in hand for TRIUMF. We note that taking the technology to significantly higher proton beam currents, such as those available at PSI, SNS, or JPARC (the Japan Proton Accelerator Research Complex), would not be possible at this time due to inability of the current technology to deal with the increased heat load. Only a demonstration of this new technology in Canada would lead the way to future, even higher density UCN sources. This is an important reason for the creation of CSUNS in its own right.

In order to operate at TRIUMF, the source will require additional infrastructure particular to the implementation in Canada, and primarily particular to the creation of a dedicated user facility at significantly increased beam power over the RCNP prototype UCN source. It is mainly this infrastructure which would be supported by CFI funds. The details of the UCN source infrastructure is described in more detail in the "budget justification" section.

2 The research cannot be supported using existing infrastructure

As stated in the previous section, and as will be described in the next section, no similar infrastructure exists in Canada or anywhere else in the world. Future sources

Applicant institution: The University of Winnipeg

Project no.: 19280

Project title: Canadian Spallation Ultracold Neutron Source

Need for the infrastructure

are planned outside Canada. The Canadian project will even surpass the future sources in its capabilities.

3 Similar Infrastructure Planned Elsewhere

No similar infrastructure is available within Canada, nor is any similar infrastructure planned for Canada. This effort is totally unique with a window of opportunity upon which we must capitalize. Even outside Canada, no other similar infrastructure is available at this time; similar infrastructure is planned in the future in other countries. In the next section, we summarize these efforts and explain how the Canadian effort would surpass them.

3.1 Summary of Other New Generation Sources

A list of new generation sources was presented in Table 1 (page 5.11), and we remind the reader of the projects in that table (acronyms explained there as well):

- * CSUNS (TRIUMF), spallation 4He, 10,000-50,000 UCN/cc.
- * ILL, CN beam 4He, 1,000 UCN/cc.
- * SNS ORNL, CN beam 4He, 150 UCN/cc.
- * Munich FRM-II, reactor SD2, 10,000 UCN/cc.
- * NCSU Pulsar, reactor SD2, 1,000 UCN/cc.
- * PSI, spallation SD2, 1,000 UCN/cc.
- * LANL, spallation SD2, 145 UCN/cc.

Of these, the LANL source is the only one currently in operation, on a testing basis.

This section is continued in the attached pages.

Applicant institution: The University of Winnipeg

Project no.: 19280

Project title: Canadian Spallation Ultracold Neutron Source

Management Plans

Criterion Standard:

The management plans provide for the optimal implementation, operation, and functionality of the infrastructure. The infrastructure requested will be managed effectively and efficiently, in keeping with the size and degree of complexity of the project.

Each of following aspects must be addressed:

1. Describe the management structure to oversee the implementation, operation, functionality and sustainability of the infrastructure.
2. Explain how the institution will address issues of access and utilization, taking into account scientific and user priorities.
3. If applicable, describe any changes or modifications to existing plans as a result of the infrastructure being requested and the integration or linkage with existing infrastructure.

1 Management Structure for Implementation, Operation, Functionality and Sustainability

The management structure for CSUNS will follow the usual structure of most medium to large scale subatomic physics experiments. The collaboration will be led by a spokesperson who is ultimately responsible for management decisions. J. Martin will serve as spokesperson through the completion of the construction and commissioning phases of the UCN source and through the completion of the first experiment on neutron decay.

Assisting the spokesperson will be an executive council consisting of members of the CSUNS collaboration. Equity on the council between Canadian and Japanese collaborators will be mandated. Once funded, we envision expanding the collaboration significantly both within Canada, and internationally, and such rules would be expanded accordingly.

The spokesperson and executive council will be responsible for the successful operation and utilization of the UCN source. Within the executive council, there will be members local to the TRIUMF facility, who will be responsible for the construction and day to day operations of the source.

W.D. Ramsay (a senior research associate in the Winnipeg/Manitoba group) is the "liaison to TRIUMF". This position would continue throughout the construction and commissioning phase of CSUNS. The liaison is responsible for communications between the CSUNS collaboration, TRIUMF management, and the relevant engineering and technical groups at TRIUMF that are involved.

Once construction of the facility begins, C. Davis (TRIUMF) will serve as the technical coordinator of CSUNS. The technical coordinator will be responsible, initially, for

Applicant institution: The University of Winnipeg

Project no.: 19280

Project title: Canadian Spallation Ultracold Neutron Source

Management Plans

overseeing the installation and construction of the UCN source. This will involve supervision of technicians and contractors who will perform the installation. Once the commissioning phase of the experiment begins, the technical coordinator would be responsible for overseeing day-to-day operations and maintenance. The technical coordinator would also be responsible for safety and liaising with the TRIUMF safety office.

A local base of individuals at TRIUMF would be responsible for managing the day-to-day operations of the UCN source. This human resource would be maintained at all times. For example, the liaison to TRIUMF and technical coordinator positions would be composed of TRIUMF scientific staff supplemented by research associates within either the Canadian or Japanese groups (similar to the way W.D. Ramsay's position is supported by NSERC subatomic physics project grants).

During installation and commissioning, Y. Masuda and several of his expert staff from Japan will be located in Canada full time to oversee the installation as well.

During the installation and commissioning process, tasks requiring the expertise of physicists will be performed with the assistance of professors, postdocs, and students from the CSUNS collaborating institutions. Overall coordination of such efforts will be overseen by the technical coordinator.

For infrastructure acquisition and development, a Gantt chart has been created showing a schedule for each major infrastructure item requested in the grant. The chart will be presented and discussed further in the financial section. Detailed physicist, engineer, and technician human resource requirements for infrastructure acquisition and development have been calculated in collaboration with TRIUMF and will be discussed in the budget justification section of the finance module. These human resource needs will be provided by a combination of CFI funds and TRIUMF.

2 Access, Utilization, and Scientific and User Priorities

Before experiments are conducted at CSUNS, their relative scientific priority must be assessed and the experiment thereby approved for access to CSUNS infrastructure. The experiments that will be conducted at CSUNS will follow the usual approval process at TRIUMF. This involves presentation of the proposed experiment to the TRIUMF Experimental Evaluation Committee (EEC) for subatomic physics. The EEC consists of international experts in subatomic physics. The committee makes a decision on the scientific priority of the experiment relative to other possible experiments. This existing structure, that has already been created by the laboratory, will be a very important way to establish the scientific credibility of the CSUNS program. The CSUNS project itself has already received approval from a special TRIUMF EEC meeting, which

Applicant institution: The University of Winnipeg

Project no.: 19280

Project title: Canadian Spallation Ultracold Neutron Source

Management Plans

focused on projects requesting approval over the course of the next TRIUMF NRC five-year funding period (2010-2015).

Once the scientific approval process is complete, scheduling of the experiments will be decided by the CSUNS collaboration in communication with the TRIUMF laboratory director, N. Lockyer.

3 Integration or Linkage with Existing Infrastructure

We have discussed the issue of integration into the existing facility at TRIUMF in great detail with the TRIUMF director, management, and with various users already conducting research at the facility (initiated through presentations at TRIUMF Users Group meetings and working group sessions). Based on these and on subsequent discussions, the concept for the implementation of the CSUNS project at TRIUMF was decided. The TRIUMF director has agreed to this plan already.

The UCN source makes use of the proton beam available from the existing TRIUMF cyclotron. The cyclotron is an H- cyclotron which has been in operation since 1974. It has provided high-intensity continuous proton beams to users for fundamental and applied research since then.

Independent beams are normally provided on one of two beam ports and proceed down beamline 1A (BL1A) and 2 (BL2). The UCN source would make use of BL1A, which proceeds east of the cyclotron into an area known as Meson Hall (see the floor plan attached to this document). That beamline is currently used by one subatomic physics experiment (called Pi-e-nu), and by condensed matter and materials scientists conducting muon spin relaxation (muSR) experiments. Pi-e-nu will be completed in 2011. After this time the installation of fabricated sections of CSUNS would proceed in the floor space vacated by Pi-e-nu.

As will be discussed in the financial section, the Meson Hall location offers CSUNS a variety of other pre-existing infrastructure that will be utilized in various ways. The most important of these is a beam dump located at the far southeast corner of the Hall. For sensitive, low-background subatomic physics experiments, it is very important to pulse the proton beam on the spallation target so that the experimental measurements can be conducted during the period when the beam is "off". At TRIUMF, this will be achieved instead by diverting the proton beam onto the CSUNS spallation target periodically using fast "kicker" magnets. The rest of the time, the beam would proceed to muSR targets and ultimately to the beam dump in Meson Hall (as it normally does now).

A side benefit of this plan is that the UCN source would only disturb the other users

Applicant institution: The University of Winnipeg

Project no.: 19280

Project title: Canadian Spallation Ultracold Neutron Source

Management Plans

in Meson Hall (muSR) a projected 7% of the time. Exactly how this is achieved will be discussed in more detail in the budget justification section of the finance module. We therefore envision that CSUNS will be a well-integrated project at the laboratory.

Applicant institution: The University of Winnipeg

Project no.: 19280

Project title: Canadian Spallation Ultracold Neutron Source

Operation and Maintenance Plans

Criterion Standard:

The plans for the optimal operation and maintenance of the proposed infrastructure for the first five years of operation are appropriate and realistic. They will allow for its sustainable usage as well as provide for future upgrade requirements.

Each of following aspects must be addressed:

1. Describe the significant requirements to efficiently operate and maintain the infrastructure (e.g., personnel, utilities, supplies, upgrades, etc.).
2. Outline the sources of support for operation and maintenance costs and describe the contingency plans should any of this support be unavailable.

1 Operations and maintenance plans

Operation of the UCN source will be the responsibility of the CSUNS collaboration. Maintenance of CSUNS will have shared responsibility with the TRIUMF laboratory. Both aspects represent the typical relationship of a research group (in this case, CSUNS) with the laboratory where the experiment is performed (TRIUMF). This relationship will now be discussed in more detail.

1.1 Operations and Maintenance Periods

The 500 MeV proton beam from the TRIUMF cyclotron is generally operated 24 hours a day, seven days a week, in eight-month periods. The remaining four months is used as a maintenance period, and for major renovations and installations. It is planned, for example, that CSUNS would be installed during a somewhat expanded maintenance period, creating as little downtime as possible for cyclotron users.

1.2 Operations when running experiments

Operation of the UCN source during the eight-month running period will likewise be conducted on a 24 hour a day basis, dependent on the run schedule of the particular experiment being conducted using CSUNS. This is in fact expected of all experiments conducted at the laboratory, to maximize the efficient use of the available proton beam. During such times, a rotating three-person shift crew will be responsible for running the UCN source and experiment. This is typically what is done, for example, at the LANL UCN source, and at other nuclear physics experiments, depending on the complexity of the experiment. The crew will be composed of members of the CSUNS collaboration, including professors, research scientists, postdocs, graduate students, and undergraduate students from all countries involved. In addition to experiment and

Applicant institution: The University of Winnipeg

Project no.: 19280

Project title: Canadian Spallation Ultracold Neutron Source

Operation and Maintenance Plans

source operations, the shift crew for the experiment is typically in continual contact with the cyclotron accelerator operators, who are responsible for delivering high-quality, intense proton beam to the experiment. The typical shift load for a collaborator on similar experiments is one month of shifts per year. Our collaboration size, supplemented by our students and postdocs, is consistent with this expectation.

Operations, when running, will be overseen by a run coordinator. This will be a rotating two-week position staffed by members of the collaboration at the PhD level or higher. The run coordinator will report to the liaison to TRIUMF, and will be responsible for communications with accelerator division at TRIUMF.

During this 24-hour a day running mode, a host of experts are available to the shift crew on an on-call basis. These are typically individuals who constructed the particular physics experiment that running at the time, and scientific staff and technicians who are responsible for the CSUNS infrastructure.

Beamline operations and maintenance will be the responsibility of the TRIUMF Accelerator Division and their technicians. This division of beamline versus experiment (in this case including the UCN source) is the usual arrangement at most laboratories. Indeed it is the Accelerator Division and accelerator operators that will control all beamline parameters when in operation.

1.3 Maintenance Personnel

The same expert users, supplemented by technicians, will be responsible for maintenance of their experimental equipment. TRIUMF scientific staff will be responsible for overseeing the maintenance of CSUNS equipment once installed at TRIUMF. However, two technicians will be necessary to maintain the infrastructure. One technician would be responsible solely for all cryogenics infrastructure (ultimately keeping the superfluid 4He at 0.8 K). The other would be responsible for all other tasks, generally maintenance of vacuum systems, of the spallation target, and for overseeing crane operations should large equipment or shielding blocks need to be moved. The requirement of two technicians is consistent with technical staff present at the LANL source. We therefore envision asking for two technicians, stationed at TRIUMF, as a part of a future CFI Infrastructure Operating Fund (IOF) request.

1.4 Utilities and Supplies

The main utility required is electricity to power equipment such as vacuum pumps, refrigerators and coolant circulating systems, monitoring equipment, and computers. Compressed air is required to operate certain valves. Such utilities would be provided

Applicant institution: The University of Winnipeg

Project no.: 19280

Project title: Canadian Spallation Ultracold Neutron Source

Operation and Maintenance Plans

by the TRIUMF laboratory in the usual fashion.

The dominant expense in supplies for the UCN source is the supply of liquid helium for cooling. A system that does not reclaim the helium is wasteful and not sustainable. The liquid helium consumption of the UCN source is 200 L/day during operation, which is the size of a typical dewar.

Fortunately, a new central helium liquifier system will be present at TRIUMF by 2011, and in discussions with TRIUMF we have negotiated to make use of this system. All helium vapour from boil-off at CSUNS will be recovered to a compressor system and then to a pressurized storage container that will feed the liquifier. Liquid helium thereby produced by the liquifier will be stored in a large dewar, which will be tapped periodically to fill a local dewar at CSUNS. This is a highly sustainable practice done at most universities and laboratories requiring large amounts liquid helium.

Nonetheless, losses from such systems occur, and we envision topping up the helium supply periodically. This would be another aspect of a future CFI IOF request.

1.5 Radiation Safety

Radiation would be produced in the UCN source, and in fact a great deal of the engineering of the spallation target and surrounding infrastructure itself goes into safely dealing with this issue. Fortunately, the issues encountered are not outside the normal scope of the TRIUMF laboratory. The laboratory currently operates a spallation target for the production of radioactive beams. Maintenance of the target would therefore be conducted according to TRIUMF policies and procedures by highly trained TRIUMF staff. This sort of maintenance would be overseen directly by the TRIUMF Environmental Health and Safety group.

1.6 Future Upgrades

Eventually, we intend to upgrade the cold moderator from solid D2O to liquid deuterium (LD2) at a temperature of 20 K. Having such a moderator would increase our UCN density by a projected factor of five. This will be pursued at a later time because this version of the source involves a significant increase in the scope of the project in terms of safety, complexity, and materials costs.

2 Sources of Support for Operations and Maintenance Costs

As discussed in the sections above, the main source for most operations and maintenance

Applicant institution: The University of Winnipeg

Project no.: 19280

Project title: Canadian Spallation Ultracold Neutron Source

Operation and Maintenance Plans

costs, particularly those related with radiation safety and the proton beamline, is TRIUMF. This is only the most natural of arrangements, given the expertise of the TRIUMF laboratory, and the typical division that occurs between beamline and experiment (in this case including the UCN source).

Where we envision requesting support from CFI IOF is primarily for the support of technicians and for periodic liquid helium top-ups accounting for our impact on the TRIUMF central helium supply. These requirements are normally outside the domain of the laboratory. This assistance would contribute to the long-term viability of the UCN source and would be unique to CSUNS. The total operations and maintenance costs will be \$150k per year as listed in the financial section. We envision IOF would pay for half these operations and maintenance costs, matched by a contribution from TRIUMF.

Applicant institution: The University of Winnipeg

Project no.: 19280

Project title: Canadian Spallation Ultracold Neutron Source

Training of Highly Qualified Personnel (HQP) Through Research

Criterion Standard:

The infrastructure requested will create or enrich a stimulating and innovative training environment that attracts high quality trainees and imparts new high-level skills to HQP for research and other careers.

Each of following aspects must be addressed:

1. Describe the benefits of the proposed infrastructure for research training and career development.
2. Outline the extent to which the proposed infrastructure will be accessed directly by research trainees.
3. Describe the impact of the proposed infrastructure on future training of HQP as well as the impact that not having access to the proposed infrastructure would have on training. Include an estimate of the number and type of HQP (e.g., undergraduate and graduate students, postdoctoral fellows, technicians, technologists, other trainees/students) to be trained.

1 Benefits of CSUNS for research training and career development

Performing research on fundamental neutron physics experiments is excellent training for problem-solving in real-world situations. Trainees in nuclear physics must use a variety of resources in order to complete complex tasks. Personnel can be trained on the design of experiments, computer simulation, design and construction of custom hardware, installation and commissioning of hardware, acquisition and analysis of data, and effective communication of progress at meetings and of results through authorship of publications. Unique technologies used in this proposal are cryogenics, vacuum technologies, nuclear instrumentation, RF technology, and superconducting technology. Many of these technologies are common to the medical field, and there is typically a large cross-over in personnel.

In addition to traditional research positions in nuclear physics, students trained in experimental nuclear physics have acquired leadership and technical positions in a variety of industries. Known to the project leader personally are those with positions in: medical physics research, materials research, quantitative analysis of the stock market, management consulting, internet start-up companies, and aerospace engineering. This incredibly diverse range of potential job opportunities, in such a large variety of technical fields, represents the range of impact possible from one who has been trained as an experimental nuclear physicist.

University of Winnipeg students trained in J. Martin's CFI-funded subatomic physics detector lab, and stationed at remote facilities such as LANL and Jefferson Lab, have received offers of employment advancing their positions in physics, and have presented at meetings of physics societies of Canada, Japan, and the U.S. This group of students includes a Rhodes Scholar, two Stevenson awardees (awarded for high academic standing and citizenship, and considered to be the top undergraduate award at the University of

Applicant institution: The University of Winnipeg

Project no.: 19280

Project title: Canadian Spallation Ultracold Neutron Source

Training of Highly Qualified Personnel (HQP) Through Research

Winnipeg), and an NSERC PGS-D awardee. Three students have been awarded NSERC USRA positions. This is a sampling of students in the past four years since Prof. Martin took up his position at the university.

1.1 Acsion Industries and Radiation Technology

As will be described in the "Collaboration and Partnerships" section and in the "Budget Justification" section of the financial module, the University of Winnipeg has partnered with a local Manitoba business, Acsion Industries, to develop a computer model of neutron transport in the UCN source. A large part of the agreement relates to the training of HQP, in this case graduate students and postdoctoral scholars from the University of Winnipeg and the University of Manitoba.

The computer simulation will be based on the Monte-Carlo N-Particle (MCNP) package. Training in writing such custom computer codes will be an integral part of the education that the students would receive. The training will open students to the possibilities available at Acsion, for which very similar techniques are used to protect the public (radiation safety and health protection consulting services), protect patients (medical products), and protect farmers and consumers (crop enhancements, food treatment, pharmaceuticals, waste products). Acsion has generated similar computer codes to model nuclear reactors. The training that students would receive could lead their careers in that direction, possibly leading to the design of new reactors for generating power.

Acsion Industries also operates its own electron beam treatment centre to commercialize specific radiation-related technologies and for training safety professionals. Access to CSUNS and TRIUMF could assist in this endeavor.

Acsion supplies consulting services in all aspects of industrial and radiation safety to utilities, engineering companies and research institutions. Our HQP would thus be well-suited for jobs in such companies.

1.2 Aboriginal Education Efforts

A common goal of the University of Winnipeg and the TRIUMF laboratory is to educate aboriginal students in basic science.

At the University of Winnipeg, this is a very important initiative due to the university's geographical location in downtown Winnipeg, a region of the city with a large aboriginal population. At TRIUMF, a scholarship has very recently been created for aboriginal students to undertake science and engineering projects as a part of

Applicant institution: The University of Winnipeg

Project no.: 19280

Project title: Canadian Spallation Ultracold Neutron Source

Training of Highly Qualified Personnel (HQP) Through Research

their education.

In 2008, the two efforts came together to support the summer research of an NSERC USRA supported aboriginal student working in J. Martin's laboratory at U. Winnipeg. The student participated in the calibration of detectors for the Q-weak experiment at Jefferson Lab. These detectors were constructed in Winnipeg, and then were taken to TRIUMF by the student to complete tests in an electron beam available there. The student's travel was supported by TRIUMF through the new scholarship. It is hoped this will be the first of a long-term relationship between TRIUMF and U. Winnipeg.

2 Direct Access of Research Trainees to CSUNS Infrastructure

As mentioned in the section "Operations and Maintenance Plans", undergraduate students, graduate students, and postdoctoral fellows would be responsible for the operation of experiments and of the UCN source. Serving data-taking shifts is one aspect of every student's experience in experimental subatomic physics.

Students and postdocs would also be responsible for a large fraction of the intellectual effort required to design the UCN source. This would be supported by the training received through Acsion Industries.

In general, students and postdocs on such projects are involved in all aspects of the projects to varying degrees, and take on responsibility for one or more smaller hardware projects related to either the particular experiment being conducted or the UCN source itself. Additionally, technicians would be trained using the infrastructure. Two technicians are required to maintain the UCN source.

3 Impact on Training HQP

The project would contribute to the training of a large number of undergraduate students, graduate students, and postdoctoral fellows from across Canada. The project has attracted a world-class group of scientists, and will therefore attract HQP from around the world to Canada. In fact, the U. Winnipeg group has already received postdoc applications citing interest in the UCN project (from ILL Grenoble and Indiana U.).

3.1 Canadian HQP

We estimate that four graduate students would complete MSc and PhD studies on the commissioning of the UCN source alone. Typically four graduate students per experiment

Applicant institution: The University of Winnipeg

Project no.: 19280

Project title: Canadian Spallation Ultracold Neutron Source

Training of Highly Qualified Personnel (HQP) Through Research

would complete MSc and PhD studies on the experiments that would eventually be conducted at CSUNS. Three postdoctoral fellows supported by Canadian institutions would be supported at any given time, and would typically be replaced in three year increments throughout the ten to twenty year experimental program at CSUNS.

3.2 International HQP in Canada

Graduate students from Japan, the U.S. and elsewhere would also be present in Canada to work at CSUNS, supported by scientists from their respective countries. We estimate that this would double the complement of graduate students and postdoctoral fellows trained at CSUNS. A unique aspect of this project would be the international environment in which our Canadian HQP would interact with students and scientists from abroad, who were attracted to Canada by the excellent science promoted here.

Applicant institution: The University of Winnipeg

Project no.: 19280

Project title: Canadian Spallation Ultracold Neutron Source

Collaborations and Partnerships

Criterion Standard:

The project will establish or enhance major collaborations and partnerships. The infrastructure requested will further strengthen multidisciplinary approaches, collaborations among researchers and users of research results, as well as partnerships with different institutions and sectors, where appropriate.

Each of following aspects must be addressed:

1. Describe the nature of the major collaborations that already exist, and that are planned, both within and external to the institution (beyond those between the principal users, as addressed in the "Researchers (Use of Infrastructure)" section in terms of:
 - a) ensuring that the proposed research or technology development can be pursued successfully;
 - b) promoting synergies among research disciplines and sectors (public, private, NFP).
2. Describe the nature of the major partnerships that already exist, and that are planned, with users of the research results, including the extent of the engagement of these partners.
3. Outline the steps that have been taken, or that will be taken, to create or strengthen collaborations, partnerships, and/or networks.
4. Explain why the proposed infrastructure is important to these collaborations or partnerships.

1 Collaborations

The University of Winnipeg is leading an international group of scientists in this world-class project in basic research. Thus far groups at Canadian universities, at TRIUMF, at KEK, at Japanese universities, and at institutions in the U.S. have joined the project. The division of "principal users" vs. "other users" is artificial in the case of this project. All other users have in fact agreed to sign this proposal, and have signed the proposal as previously presented to international review committees of the program (mentioned in the section "Quality of the Research").

1.a Ensuring Successful Research and Technology Development

J. Martin (project leader) has been responsible for this success in attracting such a distinguished list of collaborators. All of them are experts in the field of neutron physics, and are well-regarded and well-known for their achievements. The CSUNS project will bring together these excellent individuals, and bring them to Canada to conduct research. Such an impressive collaboration ensures the success of the technological development of the UCN source, and the successful completion of the cutting-edge physics experiments that will be conducted.

The collaborators have divided themselves into three major experimental collaborations:

Applicant institution: The University of Winnipeg

Project no.: 19280

Project title: Canadian Spallation Ultracold Neutron Source

Collaborations and Partnerships

neutron lifetime experiment, gravity levels experiment, and the n-EDM experiment. The Canadian users would initially work on the neutron lifetime experiment.

We now summarize the qualifications of our "other users", and their experimental interests in using the UCN source in Canada, noting that the principal users were already discussed in the "Researchers" section.

1.a.1 Japanese collaborators

Most of the Japanese collaborators have been involved in the development of the existing Japanese UCN source. These collaborators view the n-EDM experiment as their top priority once CSUNS is commissioned.

A large group spearheaded by The University of Tokyo (S. Komamiya and collaborators) has joined this effort more recently, with the goal of eventually completing a neutron gravity-levels measurement at TRIUMF. This is a very well-known group of particle physicists. S. Komamiya is the leader of the Japanese effort at LHC, for example. The group is currently developing UCN detectors with micron-scale spatial resolution to directly observe the height distribution of neutrons confined above the mirror in the experiment. This new technology, combined with the high fluxes of UCN available at TRIUMF, would enable a new precision test of gravity. The design of the experiment and of the main detector is underway in Japan.

We also note the involvement of H. Shimizu, a materials scientist from KEK. His primary interest is in use of very cold neutrons (VCN) that are also produced by the source. Neutrons of these energies can be used for condensed matter studies at relatively long wavelengths compared to traditional small-angle neutron scattering.

1.a.2 U.S. collaborators

The U.S. collaborators have been attracted because of their collective strong desire to be involved in the next big UCN project in North America.

R. Golub has been one of the main proponents of the field of UCN physics over the past several decades, and in the development of superthermal sources of UCN. He is coauthor of the seminal book "Ultra-cold Neutrons". He has already travelled to Japan to perform research using the UCN source there, and will provide expert input in the development of the spallation-driven UCN source at TRIUMF. He has expressed a strong belief that this will result in the world's highest density UCN source. He has been involved in many of the most important experiments performed using UCN over the past 30 years, for example, previous measurements of the n-EDM at ILL.

Applicant institution: The University of Winnipeg

Project no.: 19280

Project title: Canadian Spallation Ultracold Neutron Source

Collaborations and Partnerships

E. Korobkina is an expert on UCN production and storage experiments. She has designed a UCN ISR apparatus, and collaborates on the SNS EDM project, and the NCSU Pulsar reactor UCN source project. L. Clarke, a collaborator from the same group at NCSU, has also joined CSUNS in the hopes of eventually using UCN for condensed matter and surface nanoscience applications.

J.D. Bowman is a recipient of the prestigious Bonner prize of the American Physical Society. He is the main proponent of the magneto-gravitational UCN lifetime experiment.

B.W. Filippone, T.M. Ito, and B. Plaster, have most recently brought about the successful completion of the first round of physics measurements with the UCNA apparatus at LANL. They are also all collaborators on the SNS n-EDM project, and are responsible for the inner detector system and the magnetic field system. They are also involved in preparatory work towards the neutron lifetime experiment.

1.b Promoting Synergies

The CSUNS project by its very nature as a project in neutron physics is inherently multidisciplinary, and therefore promotes synergies among research disciplines. The experiments that will be done at CSUNS will probe fundamental particle physics questions through precision measurements of low-energy neutron observables. At the same time, the technology of producing UCN relies on both nuclear physics and condensed matter physics effects. The neutrons themselves, in possible future experiments, would also be used as to probe other condensed matter effects for materials science applications (the aim of users Shimizu, Korobkina, and Clarke) leading to potentially even more synergies between these different research disciplines.

The collaboration of Canadian physicists at universities and at TRIUMF with physicists at Acsion Industries (a company based in Pinawa, Manitoba) is likewise expected to be a very profitable one, and promotes a synergy between the public and private sectors in Canada. The benefits in terms of expanding the core capabilities of Acsion to computer simulations of the UCN source, and the subsequent training of HQP in Winnipeg, will be immense.

2 Major Partnerships

The partnership of Acsion Industries with the rest of the collaboration has been formalized in a memorandum of understanding (MOU) between the University of Winnipeg and Acsion. Acsion will create novel computer software to model the inner workings of the UCN source, and will provide access and training on the software thereby developed.

Applicant institution: The University of Winnipeg

Project no.: 19280

Project title: Canadian Spallation Ultracold Neutron Source

Collaborations and Partnerships

They have copious experience in this type of simulation work, having developed and used similar software to design nuclear reactors, where the neutron transport issues are very similar in nature. University of Winnipeg HQP trained in such a fashion will assist in performing a detailed optimization of the moderators in the UCN source to maximize the output UCN density. Acsion will retain the software developed as intellectual property. The intention of the company is to use the project to build their own expertise in the area of neutron transport, and potentially to market the software and their expertise to other interested parties, for example, those designing nuclear reactors for power generation. The budget in the Acsion-Winnipeg MOU will be discussed in the Financial Module.

TRIUMF is Canada's National Laboratory for Particle and Nuclear Physics and itself is a major partnership: it is owned and operated by a consortium of universities under an operating grant from the National Research Council Canada (NRC). Currently, Simon Fraser University is a member institute in the consortium, and U. Manitoba is an associate member.

This section is continued on the attached pages.

Applicant institution: The University of Winnipeg

Project no.: 19280

Project title: Canadian Spallation Ultracold Neutron Source

Benefits to Canada

Criterion Standard:

The proposed activities have the potential to lead to:

- significant improvements to society, quality of life, health, and the environment, including the development of new practices and public policies; and/or
- improved economic activities through development of new products, services and/or technologies, greater resource efficiency and productivity, and job creation in strong or emerging areas of the Canadian economy.

Each of following aspects must be addressed:

1. Describe the expected benefits to Canada, including why they are significant, how they will be realized, and the timeframe over which they are expected to be realized.
2. Describe the institution's plans to transfer the research results to potential users. Where appropriate, these should include plans for knowledge mobilization or transfer of technology and the commercialization of products, services and processes.
3. Demonstrate that the team has the skills and experience, or has identified the relevant partners, to ensure the successful transfer of the research results.

1 Expected Benefits to Canada

The Canadian Spallation Ultracold Neutron Source (CSUNS) project addresses the core principles of Canada's Science and Technology (S&T) strategy which is designed to make Canada a world leader for current and future generations. World-class excellence is promoted through the construction of the highest density UCN source in the world. The project has already attracted a large number of excellent international collaborators. The project targets an area of strength in basic research in fundamental physics, simultaneously addressing applied research in materials science, particularly surface nanoscience. Partnerships between Canada, Japan, and the U.S. clearly will be enhanced by the project, and significant funding has been committed to the CSUNS project by the Japanese contingent in the collaboration. The physics experiments that will be performed at CSUNS will likewise be funded by a combination of Canadian (NSERC) and international sources.

Canada's Science and Technology Strategy identifies three distinct Canadian S&T advantages that it aims to foster: a People Advantage, a Knowledge Advantage, and an Entrepreneurial Advantage. The UCN project addresses these priorities in the following ways:

People Advantage

* The UCN source project, coupled with the world-class physics experiments that will be

Applicant institution: The University of Winnipeg

Project no.: 19280

Project title: Canadian Spallation Ultracold Neutron Source

Benefits to Canada

conducted there, will attract excellent scientists from around the world to Canada. This is particularly true of Japanese and U.S. scientists.

* Many research opportunities for students would be created by the project. The project will train four graduate students through the commissioning of the UCN source, and four students per experiment thereafter. Typically three postdoctoral scholars would be working on projects at the UCN source at any give time. The development of a skilled workforce through basic research is a primary goal of this proposal.

* TRIUMF and the University of Winnipeg both are committed to aboriginal science education. At TRIUMF, a new initiative has been launched in aboriginal recruiting for co-op students, many of whom would be recruited for this project through recruitment efforts at the University of Winnipeg.

Knowledge Advantage

* Many of the technologies used to conduct the physics experiments are intimately linked to medical technology. For example, the Hayden research group at SFU additionally conducts research on low-field magnetic resonance imaging (MRI), because the exact same technology is used in the neutron electric dipole moment experiment.

* The UCN source can potentially be used as a tool to study advanced materials, and hence to impact the fields of materials science and surface nanoscience. One example is a possible device based on UCN inelastic scattering reflectometry (ISR). The surface nanoscience experiments that could be conducted with such a device relate to the characterization of large hydrogenous molecules for "smart surfaces", where examples in medicinal drug delivery exist. Another example results in the use of very cold neutrons (VCN, also produced by the UCN source) to study materials in a unique domain compared to traditional small-angle neutron scattering. This would potentially result in a large number of users from across the world using CSUNS to study advanced materials.

Entrepreneurial Advantage

* The UCN project has attracted the interest of a business in Pinawa, MB called Acsion Industries. Physicists at Acsion design neutron moderators for nuclear reactors, and the same technology and innovation are required for the neutron moderators used in the UCN source. Acsion scientists have already contributed to the project by beginning to study neutron transport in the UCN source. Acsion would also supply an in-kind contribution to the project. The company is involved in advanced manufacturing, based on their application of radiation technologies to manufacturing, and is involved in

Applicant institution: The University of Winnipeg

Project no.: 19280

Project title: Canadian Spallation Ultracold Neutron Source

Benefits to Canada

radiation safety and health physics.

* Another technology used extensively in the UCN source is cryogenics. Spin-offs of this technology and of the aforementioned technologies used in the physics experiments, that relate to medical applications, often result in new enterprises.

The time frame for the infrastructure development would be over the course of the next four years. After that time, experiments would be conducted and we have outlined a ten to twenty year program of experiments that would be conducted (see section "Quality of the Research or Technology Development" for a more complete description of the experiments).

The immediate goal of creation of the highest density of ultracold neutrons ever achieved in the world would therefore be completed in four to five years. The completion of the first flagship experiment, the neutron lifetime experiment, would be expected two years after that time, and would result in new knowledge on this fundamental parameter of astrophysics and would impact the standard model of particle physics. Thereafter, the neutron gravity levels experiment would be conducted, followed by a ramp-up of efforts on the n-EDM experiment. In twenty years we envision that those experiments would be completed and again new knowledge on physics beyond the standard model would be acquired.

2 Transfer of Research Results

Research results will be disseminated through scholarly journals and to the public through the media and the internet. Considerable excitement over the project is expected, as is warranted for discovery science projects of this sort. (We cite the recent press relating to the turn-on of the Large Hadron Collider LHC at CERN in Geneva, Switzerland.)

The work done by Acsion Industries has the potential for commercialization. The software that they will develop will be granted through a license to the collaboration to use through an in-kind agreement. Acsion however maintains intellectual property rights to the software that is developed. They intend to market the software to other interested parties (potentially users interested in designing nuclear reactors for power generation, or users interested in designing advanced neutron sources for condensed matter and materials science).

3 Ensuring the successful transfer of the research results

Applicant institution: The University of Winnipeg

Project no.: 19280

Project title: Canadian Spallation Ultracold Neutron Source

Benefits to Canada

All our collaborators are clearly most familiar with the dissemination of results through publications in relevant journals.

Media relations would be conducted through the relevant universities, coordinated through TRIUMF by the TRIUMF Head of Strategic Communications, Timothy Meyer.

Acsion Industries has been successful in attracting a variety of clients in related technologies in the past. They are therefore an excellent partner to assist us in technology transfer. The Canadian universities also have technology transfer offices to assist in this regard. Additionally, Advanced Applied Physics Solutions Inc. (AAPS), a not-for-profit subsidiary of TRIUMF supported by the Government of Canada's Networks of Centres of Excellence Program, has been established to assist in the commercialization of research results at TRIUMF and we envision making use of this facility as well.
